### [Anatrofin](#) - Favorite of Dan Duchaine

Dan Duchaine and [Anatrofin](#)

[Anatrofin](#) (Stenbolone) has the distinction of being Dan Duchaine's favorite steroid and so I put quite a bit of effort into researching this compound, even though it's not really on the market anymore. Being the favorite steroid of the Guru himself is enough to pique my curiosity. Unfortunately, hard data is err.. hard to come by with regards to this product, so we'll have to really examine it's structure and draw conclusions from that.

Structurally, Stenbolone actually resembles [Primobolan](#), the major difference being that instead of a 1-methyl group, it has a 2-methyl group. This is a very common alteration, and actually is the one we see when comparing [Masteron](#) and [Proviron](#). I don't see why it was done with this particular steroid, though, as it's an injectable, and this alteration is often used to increase oral availability without increasing liver-toxicity. Since it has been done, however, I'm speculating that you could actually ingest this steroid orally and still see some results. but why would you want to? Anyway, as we know, those [Masteron](#) and [Proviron](#) are very similar, but for that alteration I mentioned, so we can predict Stenbolone to actually produce very similar results to [Primobolan](#). Due to its structure (actually a 5-alpha reduced version of Boldenone), it can't aromatize to estrogen, so it can't cause estrogenic sides. However, the 1-2double bond in its structure (the same one we see with Boldenone) makes it less androgenic than I'd like and Stenbolone is only half as androgenic as Dihydrotestosterone. Thus, DHT-related [Side Effects](#) are also probably of no great concern. Clearly, this is a very safe drug in that regard, so it's easy to see why Duchaine liked it so much, stating that if he had to pick one steroid to use for the rest of his life, it would be [Anatrofin](#).

I think 100mgs injected every day or every other day would be sufficient with this drug, unfortunately, since it's no longer produced, that's pure speculation on my part, as I haven't been able to actually find anyone who has experimented with this stuff.

#### Stenbolone Acetate

[2-methyl-5alpha-androst-1-en-3-one,17b-ol]  
Molecular Weight (base): 302.4558  
Molecular Weight (ester):60.0524  
Formula (base): C20 H30 O2  
Formula (ester): C2 H4 O2  
Melting Point: N/A  
Manufacturer: Syntex (discontinued)  
Effective Dose: 350mgs-700mgs/week  
Active life: 3 days  
Androgenic/AnabolicRatio (estimate): 88:55
